

SYSTEM AND METHOD FOR DIAGNOSTIC MULTICAST SWITCHING

ABSTRACT OF THE INVENTION

5 An integrated circuit relay device and switching method are
presented that permit communications to be routed in a variety of
patterns so that diagnostic procedures can be performed in situ, to
evaluate digital wrapper communication links. The relay has a pair of
inputs, a pair of outputs, a decoder, and an encoder. The relay is
10 programmable to operate in a variety of modes, so that communications
can be passed between any set of ports, with or without encoding and
decoding processes. The flexible relay routing permits either test signals
or normal communications to be conducted through the device.
